Aim: Practical based on OOP concept using Python

IDE:

Object Oriented Programming is a fundamental concept in Python, empowering developers to build modular, maintainable, and scalable applications. By understanding the core OOP principles classes, objects, inheritance, encapsulation, polymorphism, and abstraction programmers can leverage the full potential of Python’s OOP capabilities to design elegant and efficient solutions to complex problems.

Subject: Programming With Python (01CT1309)**Aim:** Practical based on OOP concept using Python**Experiment No: 14****Date:****Enrollment No:**

- Class in Python
- Objects in Python
- Polymorphism in Python
- Encapsulation in Python
- Inheritance in Python
- Data Abstraction in Python

Python Class

A class is a collection of objects. A class contains the blueprints or the prototype from which the objects are being created. It is a logical entity that contains some attributes and methods.

Defining a Class

Example 1:

class Car:

Constructor to initialize the object

def __init__(self, brand, model):

self.brand = brand # Attribute

self.model = model # Attribute

Method to describe the car

def car_details(self):

return f"Car: {self.brand}, Model: {self.model}"

Creating an object of the Car class

my_car = Car("Toyota", "Corolla")

print(my_car.car_details())

Output:

```
In [1]: runfile('C:/Users/student/untitled0.py', wdir='C:/Users/student')
Car: Toyota, Model: Corolla
```

Example 2:

Class with Methods and Attributes

class Rectangle:

def __init__(self, width, height):

self.width = width

self.height = height

 Marwadi University Marwadi Chandarana Group	Marwadi University Faculty of Engineering & Technology Department of Information and Communication Technology	
Subject: Programming With Python (01CT1309)	Aim: Practical based on OOP concept using Python	
Experiment No: 14	Date:	Enrollment No:

```
# Method to calculate area
def area(self):
    return self.width * self.height

# Method to calculate perimeter
def perimeter(self):
    return 2 * (self.width + self.height)
```

```
# Create an object
rect = Rectangle(10, 5)
```

```
# Accessing methods
print(f'Area: {rect.area()}') # Output: Area: 50
print(f'Perimeter: {rect.perimeter()}') # Output: Perimeter: 30
Output:
```

```
In [2]: runfile('C:/Users/student/
untitled1.py', wdir='C:/Users/student')
Area: 50
Perimeter: 30
```

Encapsulation

In Python object-oriented programming, Encapsulation is one of the fundamental concepts in object-oriented programming (OOP). It describes the idea of wrapping data and the methods that work on data within one unit. This puts restrictions on accessing variables and methods directly and can prevent the accidental modification of data. To prevent accidental change, an object's variable can only be changed by an object's method. Those types of variables are known as private variables.

Example 3:

```
class BankAccount:
    def __init__(self, account_holder, balance):
        self.account_holder = account_holder
        self.__balance = balance # Private attribute
```

 Marwadi University Marwadi Chandarana Group 	Marwadi University Faculty of Engineering & Technology Department of Information and Communication Technology	
Subject: Programming With Python (01CT1309)	Aim: Practical based on OOP concept using Python	
Experiment No: 14	Date:	Enrollment No:

```
def deposit(self, amount):
    self.__balance += amount
def withdraw(self, amount):
    if amount <= self.__balance:
        self.__balance -= amount
    else:
        print("Insufficient funds")
def get_balance(self):
    return self.__balance
# Create an account
account = BankAccount("John", 1000)
account.deposit(500)
print(account.get_balance()) #
account.withdraw(700)
print(account.get_balance()) #
Output
```

```
In [3]: runfile('C:/Users/student/Desktop/PWP
Practical/OOP_3.py', wdir='C:/Users/student/
Desktop/PWP Practical')
1500
800
```

Inheritance

Inheritance allows a new class (child class) to inherit attributes and methods from an existing class (parent class). It promotes code reusability.

Example 4

class Animal:

```
def __init__(self, name):
    self.name = name
def speak(self):
    return "I am an animal."
```

Dog class inherits from Animal class

```
class Dog(Animal):
    def speak(self):
        return f"{self.name} says Woof!"
```

Cat class inherits from Animal class

```
class Cat(Animal):
    def speak(self):
```

 Marwadi University Marwadi Chandarana Group 	Marwadi University Faculty of Engineering & Technology Department of Information and Communication Technology	
Subject: Programming With Python (01CT1309)	Aim: Practical based on OOP concept using Python	
Experiment No: 14	Date:	Enrollment No:

```

    return f"{self.name} says Meow!"
dog = Dog("Buddy")
cat = Cat("Whiskers")
print(dog.speak()) #
print(cat.speak()) #
Output

```

```

In [4]: runfile('C:/Users/student/Desktop/PWP
Practical/OOP_4.py', wdir='C:/Users/student/
Desktop/PWP Practical')
Buddy says Woof!
Whiskers says Meow!

```

Polymorphism

Polymorphism is another important concept of object-oriented programming. It simply means more than one form.

That is, the same entity (method or operator or object) can perform different operations in different scenarios.

Example 5:

```

class Polygon:
    # method to render a shape
    def render(self):
        print("Rendering Polygon...")
class Square(Polygon):
    # renders Square
    def render(self):
        print("Rendering Square...")
class Circle(Polygon):
    # renders circle
    def render(self):
        print("Rendering Circle...")

```

```

# create an object of Square
s1 = Square()
s1.render()
# create an object of Circle
c1 = Circle()
c1.render()
Output:

```

 Marwadi University Marwadi Chandarana Group 	Marwadi University Faculty of Engineering & Technology Department of Information and Communication Technology	
Subject: Programming With Python (01CT1309)	Aim: Practical based on OOP concept using Python	
Experiment No: 14	Date:	Enrollment No:

```
In [5]: runfile('C:/Users/student/Desktop/PWP
Practical/OOP 5.py', wdir='C:/Users/student/
Desktop/PWP Practical')
Rendering Square...
Rendering Circle...
```

Abstraction

Abstraction focuses on hiding the internal implementation details of a class and exposing only the essential features.

Example 6:

from abc import ABC, abstractmethod

Abstract class

```
class Shape(ABC):
    @abstractmethod
    def area(self):
        pass
```

```
class Circle(Shape):
    def __init__(self, radius):
        self.radius = radius
```

```
    def area(self):
        return 3.14 * self.radius * self.radius
```

```
circle = Circle(5)
print(f"Area of the circle: {circle.area()}") #
```

Output:

```
In [6]: runfile('C:/Users/student/Desktop/PWP
Practical/OOP 6.py', wdir='C:/Users/student/
Desktop/PWP Practical')
Area of the circle: 78.5
```

Post Lab Exercise:

- Write a Python program to create a class representing a Circle. Include methods to calculate its area and perimeter.

Code :

```
import math
```

```
class Circle:
```

```
    def __init__(self, radius):
```

 Marwadi University Marwadi Chandarana Group	Marwadi University Faculty of Engineering & Technology Department of Information and Communication Technology	
Subject: Programming With Python (01CT1309)	Aim: Practical based on OOP concept using Python	
Experiment No: 14	Date:	Enrollment No:

```

self.radius = radius
def area(self):
    return math.pi * (self.radius ** 2)
def perimeter(self):
    return 2 * math.pi * self.radius
circle = Circle(5)
print("Area of the circle:", circle.area())
print("Perimeter of the circle:", circle.perimeter())

```

Output :

```

In [7]: runfile('C:/Users/student/Desktop/PWP
Pratical/OOP_7.py', wdir='C:/Users/student/
Desktop/PWP Pratical')
Area of the circle: 78.53981633974483
Perimeter of the circle: 31.41592653589793

```

- Create a class `Book` that stores details like the title, author, and price of a book. Add methods to display the details of the book and apply a discount to the price. (a) Create two objects for different books and display their details. (b) Apply a 10% discount to one of the books and display the updated price.

Code :

class Book:

```
def __init__(self, title, author, price):
```

```
    self.title = title
```

```
    self.author = author
```

```
    self.price = price
```

```
def display_details(self):
```

```
    print(f"Title: {self.title}")
```

```
    print(f"Author: {self.author}")
```

```
    print(f"Price: ${self.price:.2f}")
```

 Marwadi University Marwadi Chandarana Group	Marwadi University Faculty of Engineering & Technology Department of Information and Communication Technology	
Subject: Programming With Python (01CT1309)	Aim: Practical based on OOP concept using Python	
Experiment No: 14	Date:	Enrollment No:

```
def apply_discount(self, discount_percentage):
```

```
    self.price -= self.price * (discount_percentage / 100)
```

```
book1 = Book("To Kill a Mockingbird", "Harper Lee", 29.99)
```

```
book2 = Book("1984", "George Orwell", 24.99)
```

```
print("Details of Book 1:")
```

```
book1.display_details()
```

```
print("\nDetails of Book 2:")
```

```
book2.display_details()
```

```
book2.apply_discount(10)
```

```
print("\nDetails of Book 2 after applying a 10% discount:")
```

```
book2.display_details()
```

Output :

```
In [8]: runfile('C:/Users/student/Desktop/PWP
Practical/OOP_8.py', wdir='C:/Users/student/
Desktop/PWP Practical')
Details of Book 1:
Title: To Kill a Mockingbird
Author: Harper Lee
Price: $29.99

Details of Book 2:
Title: 1984
Author: George Orwell
Price: $24.99

Details of Book 2 after applying a 10%
discount:
Title: 1984
Author: George Orwell
Price: $22.49
```
